

HOW THE BOOKS TEACH

Five steps, every time

Every worked example in all three volumes. One shape.

1 · Setup

The situation and every input, stated before any arithmetic. If a number is not here, it does not appear later.

2 · Formula

The relationship, written out. Not a spreadsheet cell reference — the actual expression, so it can be checked away from the tool.

3 · Substitution

The inputs put into the formula. This is the step most textbooks skip, and it is the step where errors are actually caught.

4 · Result

The number, at a stated precision, with its units.

5 · Interpretation

What it means, what it does *not* mean, and what a professional would do next. A correct number that leads to the wrong decision has failed.

15,613

Machine checks in PFL-AI and PML-AI, all passing. Every printed result is recomputed from its inputs and compared to the page, and the suite is fail-closed: a domain does not pass gate until it passes in full.

INCLUDING

Every multiple-choice option.
Not only the correct one.

A plausible wrong answer that is arithmetically impossible teaches nothing.
