1. Executive summary

Project controls is not reporting. Reporting describes what has already happened. Project controls is the discipline of **knowing early enough to act** — converting the physical and commercial reality of a project into a defensible position, a defensible forecast, and a decision that changes the outcome while changing it is still possible.

That distinction is the whole subject. It is also where most organisations lose money.

This publication summarises the **PCP-AI Body of Knowledge**: thirteen domains and sixty-one knowledge areas, weighted 40% financial reporting and accounting, 40% project management and delivery, 20% artificial intelligence. It is written for people who commission, fund, govern or lead project delivery, and who need to judge whether their control function is working.

Six findings frame everything that follows.

One. The value of a control system is the speed of its full loop, not the accuracy of its reports. A number that is right and late has no value. Section 4 sets out the six conversions a control system performs, and where each one leaks.

Two. Control effectiveness is multiplicative, not additive. Fidelity, timeliness and authority multiply. If nobody is accountable for acting on a variance, the quality of the variance calculation is irrelevant. Section 5 makes this quantitative.

Three. The most expensive failures are the quietest. The characteristic failure of project controls is not an obviously wrong report. It is a confident, well-formatted, internally consistent report built on an un-accrued commitment or a subjective progress claim. Section 6 names seven of these and gives a detection test for each.

Four. Financial literacy is not optional for controls professionals. Projects are settled in accounting outcomes — revenue recognised, provisions booked, contract assets and liabilities carried on a balance sheet. A controls function that cannot reconcile to the finance ledger is producing a parallel set of books. This is why the Body of Knowledge weights finance at 40%.

Five. AI changes the cost of analysis, not the location of accountability. AI is now genuinely useful in project controls: anomaly detection across a cost ledger, first-draft commentary, schedule-logic screening, document extraction. None of it transfers accountability. Section 12 sets out an assurance ladder that places each task by the consequence of an undetected error, not by what the technology can do.

Six. Most organisations self-assess two levels above where they operate. They produce forecasts, so they believe they are forecasting. The test is not whether a forecast exists. It is whether last quarter's forecast changed a decision. Section 13 provides the maturity model and the diagnostic.

The one-sentence version. Project controls earns its cost only at the point where a forecast becomes a decision — everything upstream of that point is preparation, and everything downstream is history.

2. What project controls actually is

Project controls is the integrated set of processes by which an organisation establishes what a project is meant to cost and deliver, measures what it is actually costing and delivering, forecasts where it will end, and informs the decisions that close the gap.

It sits deliberately between two functions and is frequently confused with both.

	Finance		Project management
Primary question	What must we report?	Where will this end, and what must change?	How do we execute the work?
Time orientation	Backward — closed periods	Forward — open decisions	Present — current activity
Unit of account	Legal entity, period	Control account, project	Work package, activity
Governing standard	IFRS / local GAAP	Measurement and forecasting discipline	Method and lifecycle
Accountable for	Accuracy of the record	Reliability of the forward view	Delivery of the scope
Fails by	Misstatement	Late warning	Missed execution

The distinction that matters most is the third row. Finance is authoritative about closed periods. Project controls is accountable for the open ones. A controls function that spends its month producing a beautiful reconciliation of what already happened has quietly become a second finance department.

The boundary test. If your controls output would be equally valid published a month late, it is reporting, not control.

Figure 1 — suggested diagram. Three overlapping vertical bands (Finance · Project Controls · Project Management) on a left-to-right time axis running past → present → future. Finance shaded over the past, project management over the present, project controls spanning present into future. One annotation arrow labelled "the decision window" sits where controls overlaps the future.

3. Why this matters

The case for project controls does not need overstatement. The published evidence is sufficient.

Bent Flyvbjerg's research programme, drawing on a database of more than 16,000 projects across sectors and continents, reports that a small minority of projects deliver on cost and schedule together, and a far smaller minority deliver on cost, schedule and benefits together (Flyvbjerg and Gardner, *How Big Things Get Done*, 2023). His earlier work on transport infrastructure found cost overruns in the large majority of projects examined, and — critically — no evidence that forecasting accuracy had improved over the seventy years of data (Flyvbjerg, Holm and Buhl, 2002).

The McKinsey Global Institute's analysis of construction found labour productivity in the sector growing at roughly a third of the rate of the world economy over two decades (*Reinventing Construction*, 2017).

Two conclusions follow, and they are more useful than the headline numbers.

First, the problem is not measurement technology. The seventy-year flatness of forecasting accuracy spans the introduction of critical path method, earned value management, enterprise resource planning, integrated project controls software and cloud analytics. Each was a genuine advance in capability. None moved the aggregate outcome. That should make any organisation sceptical of the claim that a new tool will fix its forecasting.

Second, the failure is concentrated at the ends of the loop — in how reality enters the system, and in whether the output changes a decision. Those are the two conversions least served by software and most dependent on professional discipline.

Callout. The consistent finding across the literature is not that projects are hard to forecast. It is that organisations act on forecasts too late. The constraint is decision latency, not analytical capability.

What this costs, concretely. On a project of 420 million, a forecasting error of 8% that surfaces at month 14 of 30 leaves sixteen months to respond. The same error surfacing at month 24 leaves six. The error is identical; the options are not. Section 16 works this through with figures.

4. The Controls Value Chain

Original framework.

A control system performs six conversions. Each one loses some fidelity and adds some latency. The performance of the whole system is governed by the weakest conversion and the sum of the delays — not by the sophistication of any single stage.

#	Conversion	Question answered	Characteristic failure	Typical latency
1	Reality → Record	What has actually happened?	Cut-off gap; commitments received but not accrued	Days to weeks
2	Record → Structure	Where does it belong?	Miscoding; WBS and CBS drift apart	Hours to days
3	Structure → Position	Where are we now?	Progress claimed by opinion, not by rule	Weekly to monthly
4	Position → Forecast	Where will we end?	Single-point EAC; assumption left unstated	Monthly
5	Forecast → Decision	What must change?	Report issued to a distribution list, no named owner	Days to months
6	Decision → Reality	Did anything change?	Decision never lands in the baseline or the commitment	Weeks

The asymmetry that costs money. Investment concentrates on conversions 3 and 4 — dashboards, EVM engines, forecasting tools. These are the visible, purchasable parts of the chain. Conversions 1 and 6, the two that touch physical and commercial reality, are the least governed and the most damaging when they fail.

Conversion 1 fails silently: a cost that has been incurred but not recorded makes every downstream index look better than the truth. Conversion 6 fails invisibly: a decision that never reaches the baseline means the next period's variance is measured against a plan nobody is working to.

Total control latency is the sum of the six. An organisation reporting monthly, with a five-day close, a two-week review cycle and no standing decision forum, is routinely operating on a forward view that is six to ten weeks old. On a thirty-month project that is a meaningful fraction of the remaining decision window.

Figure 2 — suggested diagram. A closed hexagonal loop, six nodes labelled with the conversions above, arrows running clockwise back into node 1. Each arrow carries a small latency label. Nodes 1 and 6 rendered in an accent colour with the caption "least governed, most damaging". A dashed line across the middle labelled "where software helps" enclosing only nodes 2, 3 and 4.

5. The Control Effectiveness Equation

Original framework.

Organisations invest in project controls as though effectiveness were additive — better data, plus better tooling, plus better reports. It is not. It is multiplicative.

$$E = F \times T \times A$$

Fidelity (F) — does the number represent reality? **Timeliness (T)** — does it arrive while the decision is still open? **Authority (A)** — is there a named person who can act, and did they?

Each term runs from 0 to 1. Effectiveness is their product.

The model is a heuristic, not a measurement instrument. Its purpose is to force a specific question: which term is binding?

Worked illustration. A controls function assesses itself honestly: its numbers are good but not perfect ($F = 0.9$); its reporting lands roughly two weeks after the decision point on about a fifth of decisions ($T = 0.8$); half of its variances have no named owner ($A = 0.5$).

Scenario	F	T	A	E
Current state	0.90	0.80	0.50	0.36
Invest in data quality	0.95	0.80	0.50	0.38
Assign owners to every variance	0.90	0.80	0.90	0.65

The data-quality programme — expensive, technical, visible, and the one most often funded — adds two points. Assigning a named owner to every variance, which costs a governance decision and a column in a register, adds twenty-nine.

This is not an argument against data quality. It is an argument for diagnosing the binding constraint before spending. Fidelity work is correct when F is genuinely low, which it is in many organisations. It is misdirected when F is 0.9 and A is 0.5.

Callout — the zero test. If any term is zero, effectiveness is zero regardless of the others. A perfect forecast delivered after the concrete is poured has $T = 0$. A perfect, timely forecast issued to a distribution list with no accountable recipient has $A = 0$. Both are complete write-offs of the controls budget, and both are common.

How to estimate the terms. F : sample ten control accounts and reconcile to source. T : measure the gap between data date and the decision forum that uses it. A : count the proportion of open variances with a named individual and a due date.

Figure 3 — suggested diagram. Three vertical sliders (Fidelity, Timeliness, Authority) with a product readout beneath. Two states shown side by side — "current" and "after governance fix" — with the multiplier result rendered large. Emphasise the disproportion visually.

6. Current industry challenges — the Seven Silent Failures

Original framework.

These failures share one property: **they do not produce an obviously wrong report.** They produce a confident, plausible, internally consistent report that is wrong. That is why they survive review, and why they are expensive.

#	Silent failure	What it looks like	Why it survives	Detection test
1	The cut-off gap	Cost performance improves in the reporting month, deteriorates in the following one	The ledger balances; nothing looks missing	Compare goods-received-not-invoiced to the accrual booked. A persistent gap is the failure
2	Progress by opinion	Percentage complete supplied by the party being measured	Everyone reports something; the number is never blank	Ask what physical rule generated the figure. If the answer is a judgement, it is not a measurement
3	The single-point forecast	One EAC, quoted to the nearest thousand, with no stated assumption	Precision is mistaken for accuracy	Ask which of the three EAC assumptions it rests on. If nobody can say, there is no forecast
4	The orphan variance	The same variance appears in three consecutive reports, unchanged	Reporting it feels like managing it	Count open variances with a named owner and a due date
5	Baseline drift	Approved changes executed but never rebaselined	The team is working to a plan the system does not hold	Reconcile the sum of approved change to the delta between original and current baseline
6	The reconciliation gap	Controls cost and finance cost differ, and the difference is "explained" each month	The explanation is stable, so it reads as understood	Require the difference to be itemised, not characterised
7	The unexamined machine	AI-generated commentary or forecast accepted because it reads well	Fluency is read as competence	Require the verification step and the name of the person who performed it

The common root. Six of the seven are failures of conversion 1 or conversion 5 in the value chain — reality entering the system, or the system reaching a decision. Only the third is a genuine analysis failure.

Callout. A report that has never been wrong in a way anyone noticed is not necessarily accurate. It may simply be unfalsifiable. Build at least one falsifiable claim into every reporting cycle — a forecast with a date and a number that can later be scored.

7. The architecture of the Body of Knowledge

The PCP-AI Body of Knowledge is organised as **thirteen domains containing sixty-one knowledge areas**, grouped into three competency areas.

Area	Competency	Weighting	Domains
A	Financial reporting and accounting	40%	1, 2, 5, 7, 11
B	Project management, controls and delivery	40%	3, 4, 6, 8, 9, 10, 12
C	AI for project controls	20%	13, plus embedded coverage in every other domain

The three literacies. The weighting is not arbitrary. It reflects three distinct literacies a modern controls professional must hold simultaneously.

Financial literacy (40%) — the language in which project outcomes are ultimately settled. A project does not end in a dashboard. It ends in recognised revenue, booked provisions, contract assets and liabilities, and a final account. A controls professional who cannot follow a cost from commitment through accrual to recognised revenue cannot explain their own numbers to a board.

Delivery literacy (40%) — the mechanics by which work becomes measurable value. Baselines, earned value, critical path, change control, risk quantification, and the adaptive methods now used alongside them.

Machine literacy (20%) — the judgement required to supervise tools that are now embedded in both of the above. Not how to build a model. How to interrogate one, and when to refuse its output.

Callout — how the AI weighting is carried. The 20% is not confined to Domain 13. Every non-AI domain carries an "AI in this domain" treatment, and Domain 13 provides systematic per-domain coverage. The weighting is measured across that whole surface. AI is treated as a property of the discipline, not an appendix to it.

Mapping the domains to the value chain. The thirteen domains are not a list of topics. They map onto the six conversions of Section 4.

Conversion	Domains that govern it
1 · Reality → Record	1 (accounting foundations), 5 (cost control cycle), 11 (process cycles)
2 · Record → Structure	1 (cost coding), 5 (CBS and control accounts), 8 (WBS)
3 · Structure → Position	4 (performance and variance), 6 (earned value), 10 (schedule progress)
4 · Position → Forecast	3 (budgeting and forecasting), 6 (EAC family), 12 (risk and contingency)
5 · Forecast → Decision	4 (management reporting), 8 (monitoring and controlling), 9 (agile governance)
6 · Decision → Reality	5 (change control), 7 (contracts and commercial), 8 (integrated change control)
Across all six	2 (reporting standards), 13 (AI), 12 (risk)

Figure 4 — suggested diagram. The hexagonal loop from Figure 2, with domain numbers plotted around it as labelled satellites, sized by indicative examination weighting. Colour-code by competency area (A / B / C).
Caption: "Thirteen domains, one loop."

8. Area A — Financial reporting and accounting (40%)

Five domains. This is the area most often under-weighted in project controls training, and the one that most often causes a controls function to lose credibility with a board.

Domain 1 · Foundations of accounting for project controls (~8%). The accounting model, double-entry mechanics, the financial statements and what each shows, accrual accounting and the matching concept, provisions versus accruals, and the chart of accounts and cost coding that map project structure to financial structure.

Domain 2 · Financial reporting and the standards (~12%) — the largest single domain. The reporting framework, and IFRS 15 Revenue from Contracts with Customers treated in depth as the flagship knowledge area: the five-step model, and its application to long-term contracts. Then revenue beyond the basics — principal versus agent, bundled obligations — IAS 37 provisions and contingent liabilities, the asset and lease standards where they touch project cost, and the distinction between management and statutory reporting.

Domain 5 · Cost management and cost control (~8%). Cost types and drivers, allocation and overhead recovery, and the cost control cycle that carries a cost from **commitment** → **accrual** → **actual**. Cost breakdown structures, control accounts and work packages. Change control and its cost effect.

Domain 7 · Contracts, commercial management, BoQ, invoicing and revenue (~8%). Contract types and the risk each allocates — lump sum, remeasurement, cost-plus, target-cost with pain-gain, framework and EPC. Contract lifecycle management, claims, liquidated damages, retention and bonds.

Bills of quantities and measurement. Interim valuations and applications for payment. Over- and under-billing, and the contract asset and liability positions that result.

Domain 11 · Business process cycles (~4%). Order-to-cash and procure-to-pay end to end, the controls embedded in each, segregation of duties, and the audit trail.

Callout — why finance is 40%. The single most common credibility failure for a controls function is an inability to reconcile its position to the finance ledger. When controls says one number and finance says another, the controls number loses — not because it is wrong, but because it is not the one the accounts are prepared on. Reconciliation is a controls competency, not a finance favour.

The conversion this area governs. Domains 1, 5, 7 and 11 own conversion 1 — how reality enters the record. Domain 2 governs how that record becomes an external truth. Read against Section 6, this area contains the antidote to Silent Failures 1, 5 and 6.

9. Area B — Project management, controls and delivery (40%)

Seven domains covering the mechanics of measurement, forecasting and delivery.

Domain 3 · Budgeting and forecasting (~7%). Top-down, bottom-up and zero-based budgeting; contingency and management reserve. Estimate classes and accuracy ranges, and the basis of estimate. The time-phased cost baseline and the S-curve. Forecasting methods and rolling forecasts. Cash flow forecasting and funding.

Domain 4 · Performance management, variance analysis and reporting (~6%). KPIs, thresholds and tolerances; leading versus lagging indicators. Variance analysis including the full bridge from budget to actual. Report design, cadence, audience and exception reporting. Data visualisation, and the distortions to avoid.

Domain 6 · Earned value management and forecasting (~8%). Planned value, earned value and actual cost; the measurement methods that determine how progress is earned. Variances and indices — CV, SV, CPI, SPI, TCPI. The **EAC family** and, decisively, when each formula is the defensible one. Integration of cost and schedule, the limits of EVM, and the earned schedule concept.

Domain 8 · Project management lifecycle (~6%). Initiating through closing, with a threaded case running one project across all five process groups. Development approaches across the predictive-to-adaptive spectrum, and the distinction between incremental and iterative delivery.

Domain 9 · Agile, Scrum and adaptive delivery for project controls (~5%). Agile foundations and empirical process control. Scrum in depth. Backlogs, relative estimation and flow metrics. Kanban, Lean and scaling at awareness level. Then the crux for this profession: **cost control, forecasting and earned value in adaptive delivery** — funding models, run-rate, and how to report against a phase gate when execution runs in sprints. Hybrid governance and contracting for agile.

Domain 10 · Project scheduling (~4%). Activity definition and sequencing, dependency types, leads and lags. Network analysis and critical path method with forward and backward pass, total and free float. Compression through crashing and fast-tracking; resource levelling and smoothing; schedule risk. Progress measurement and schedule control.

Domain 12 · Risk management for project controls (~4%). ISO 31000 principles, risk appetite and tolerance. The full risk process including quantitative analysis and expected value. Contingency and management reserve, and the link back to the budget.

Callout — the EAC point. Three teams with identical data can produce three different estimates at completion, and all three can be correct. The formula is not the difficulty. The professional judgement is selecting the assumption the forecast rests on — is the variance structural or a one-off, and does the remaining work resemble the work done — and defending that assumption to a board. A forecast that cannot be defended is a guess with decimal places.

10. Area C — AI for project controls (20%)

One dedicated domain, plus systematic coverage embedded across the other twelve.

Domain 13 · AI for project controls and project management (~20%). Seven knowledge areas:

KA	Knowledge area	Core content
13.1	AI foundations for professionals	What AI, machine learning and generative AI are; learning paradigms at working level; how language models generate; capabilities and limits
13.2	Data — the fuel	Quality, structure, governance and lineage; project-controls data sources; why data condition dominates AI outcomes
13.3	Prompting and working with generative AI	Structured prompts, context and examples, iterative refinement, and verification of outputs
13.4	AI tool categories	Vendor-neutral survey by category: what each does, typical inputs and outputs, and governance notes
13.5	AI applied across the lifecycle	The core of the domain — hands-on workflows across estimating, cost, schedule, risk, commercial and reporting
13.6	Governance, ethics, risk and assurance	Human accountability and sign-off; auditability; the trail of what AI produced and who approved it
13.7	Building an AI-augmented capability	Maturity, integration, upskilling, measuring value, and change management

The governing principle, stated once and applied everywhere:

AI proposes. The professional disposes.

This is not a slogan about caution. It is a statement about where accountability sits. An estimate, a forecast, a commitment or a certification carries a professional's name. The tool that helped produce it does not acquire a share of that responsibility, and cannot be cited in its defence.

11. Where AI genuinely changes controls work

An honest assessment separates three categories. Most commentary collapses them.

Category	Meaning	Examples in project controls
Genuine change today	Materially faster or newly feasible, with verification	Anomaly detection across a cost ledger; extraction from unstructured contract and invoice documents; schedule-logic screening (open ends, negative lag, constraint abuse); first-draft variance commentary; natural-language querying of controls data
Emerging, with caveats	Real but sensitive to data condition	Predictive EAC and early-warning models; driver analysis; scenario generation; risk identification from historical data
Overstated	Claimed more often than demonstrated	Autonomous forecasting without human sign-off; "AI-generated schedules" fit for execution; judgement substitution in claims, contract interpretation or certification

The pattern. AI performs best where the task is high-volume pattern recognition against a defined rule — screening ten thousand ledger lines for anomalies, or a four-thousand-activity schedule for logic defects. It performs worst where the task is low-volume, high-consequence judgement under ambiguity — which is most of what senior controls professionals are paid for.

The data constraint is the real constraint. Predictive models in project controls are trained on an organisation's historical project data. Most organisations' historical data carries the Silent Failures of Section 6 — un-accrued costs, opinion-based progress, drifted baselines. A model trained on that data learns to reproduce the organisation's historical optimism with greater confidence and better formatting.

Callout. Fixing conversion 1 is a prerequisite for AI in project controls, not a parallel workstream. An organisation that cannot trust its cost ledger cannot trust a model trained on it. The order of operations is not negotiable.

The verification cost is real and must be budgeted. An AI-drafted commentary that takes two minutes to generate and twenty minutes to verify has not saved eighteen minutes of work — it has changed the shape of the work. Where verification is skipped because the output reads well, the tool has produced a net loss disguised as efficiency. That is Silent Failure 7.

12. The AI Assurance Ladder

Original framework.

The governing question is not "can the tool do this?" It is "**what happens if this output is wrong and nobody notices?**" The rung is set by consequence, not capability.

Rung	Level	Human role	Appropriate when	Controls examples
L0	Prohibited	AI not used	Output carries a professional certification, legal position or attestation	Certifying a payment application; signing a final account; a claim position
L1	Assistive	Human authors; AI drafts structure or language	Consequence high, but human writes the substance	Drafting a report narrative; restructuring a basis of estimate
L2	Analytical	AI detects; human verifies every flag	High volume, defined rule, verifiable output	Ledger anomaly detection; schedule-logic screening; document extraction
L3	Advisory	AI proposes a number; human tests and signs	Output feeds a decision but is reviewable against method	Predictive EAC as a challenge to the manual forecast; risk scoring
L4	Automated with assurance	AI executes; humans sample and audit	Routine, repetitive, low unit consequence, aggregate monitored	Cost coding and classification; invoice matching; data-quality checks
L5	Autonomous	No human in the loop	Not permitted for any output carrying professional accountability	—

The placement rule. A task's rung is the lowest rung justified by these three tests:

1. **Consequence** — if this is wrong and undetected for one reporting cycle, what is the exposure?
2. **Verifiability** — can a competent professional check the output against a defined method in reasonable time?
3. **Reversibility** — if the error is found next quarter, can it be corrected without a write-off or a legal position?

If consequence is high and verifiability is low, the answer is L0 or L1 — regardless of how impressive the demonstration was.

Figure 5 — suggested diagram. A vertical ladder, six rungs, ascending autonomy. A shaded band across L0–L3 labelled "human signs". L5 struck through, captioned "not permitted for accountable outputs". To the right, a three-question decision tree feeding arrows onto the correct rung.

The audit trail requirement. At every rung above L0, three things must be recorded: what the tool was asked, what it produced, and who accepted it. Without that trail, a future review cannot distinguish professional judgement from unexamined machine output — and neither can a regulator, an auditor or a tribunal.

13. The Controls Maturity Model

Original framework.

Five levels. Each level is defined by a **capability that is demonstrably present**, not by tooling owned or processes documented.

Level	Name	The organisation can say	Evidence that it is real	Dominant risk at this level
1	Recording	"We know what we have spent."	Cost ledger reconciles to finance	Cost is known but late; no forward view
2	Reporting	"We can describe the past accurately."	Consistent period reporting, explained variances	Confident description of a position already superseded
3	Measuring	"We know our true position now."	Accruals complete; progress by physical rule; controls reconciles to finance without a standing difference	Accurate present, unstated future
4	Forecasting	"We know the range of outcomes and the assumptions beneath them."	EAC range with named assumptions; forecasts scored against actuals	Forecasts produced, not used
5	Steering	"Our forecasts change decisions early enough to change results."	Documented decisions traceable to a specific forecast, and re-baselined	Complacency; drift back to Level 2 under schedule pressure

The diagnostic that matters. Most organisations self-assess at Level 4 and operate at Level 2. The reason is that Level 4 is defined in most maturity models by the production of a forecast, which is easy, rather than by its quality and use, which is not.

Three questions separate the levels honestly:

1. **Level 3 test.** Take last month's cost position. Does it reconcile to the finance ledger with an itemised — not characterised — difference?
2. **Level 4 test.** Take a forecast issued six months ago. Score it against actuals. Does anyone routinely do this?
3. **Level 5 test.** Name a decision made in the last quarter that was caused by a controls forecast, and show where it landed in the baseline.

If question 3 has no answer, the organisation is not steering, whatever its tooling.

Callout. Maturity is not cumulative by default. Level 5 organisations fall back to Level 2 under schedule pressure, because describing the past is the least contentious thing a controls function can do. Maturity has to be defended, not just achieved.

Figure 6 — suggested diagram. A five-step ascending staircase. Each step carries its name, its one-line claim, and its evidence test. A dashed downward arrow from step 5 to step 2 labelled "regression under pressure". A shaded band showing "self-assessed" hovering two steps above "demonstrated".

14. Best practice — the twelve disciplines

Two disciplines per conversion. Each is a practice, not a principle — it can be adopted, evidenced and audited.

Conversion 1 · Reality → Record

1. **Accrue by rule, not by memory.** Every reporting period, reconcile goods-received-not-invoiced against booked accruals, and itemise the difference.
2. **Fix the cut-off date and publish it.** A cut-off that moves to accommodate late data destroys period comparability.

Conversion 2 · Record → Structure

1. **One structure, mapped both ways.** WBS, CBS and control accounts must reconcile to the chart of accounts in a documented mapping, reviewed when either side changes.
2. **Code at the point of commitment.** Coding applied at invoice stage is coding applied too late to influence anything.

Conversion 3 · Structure → Position

1. **Earn progress by physical rule.** Define the measurement method per work package before work starts — milestone, units complete, or a defined weighting. Never accept a percentage supplied by the party being measured.
2. **Reconcile to finance every period, without exception.** A standing unreconciled difference is a second set of books.

Conversion 4 · Position → Forecast

1. **Forecast in a range with named assumptions.** Publish at least two EAC scenarios and state which assumption each rests on.
2. **Score your forecasts.** Retain past forecasts and compare them to outturn. An unscored forecasting process cannot improve.

Conversion 5 · Forecast → Decision

1. **Every variance has a name and a date.** No exceptions, and count the exceptions monthly.
2. **Report exceptions, not everything.** A forty-page pack read by nobody has an authority term of zero.

Conversion 6 · Decision → Reality

1. **Close the loop into the baseline.** An approved change that has not moved the baseline has not been implemented.
2. **Audit the trail, including the machine's part in it.** Record what AI produced and who accepted it, at every rung above L0.

Callout. Ten of these twelve cost governance attention rather than capital expenditure. That is the point. The binding constraint in most controls functions is not tooling.

15. Implementation roadmap

Three phases, three gates, twelve months. Each gate is a **demonstrated capability**, not a completed document.

Phase 1 · Days 0-90 — Diagnose and stabilise the record

Objective. Establish whether the numbers are true. Nothing downstream matters until this is settled.

- Sample ten control accounts and reconcile end to end, from source document to reported position.
- Measure the cut-off gap: goods-received-not-invoiced against accruals booked, for the last three periods.
- Inventory progress measurement methods by work package. Classify each as rule-based or opinion-based.
- Establish the current position on the Control Effectiveness Equation — estimate F, T and A honestly.

Gate 1. The controls cost position reconciles to the finance ledger with an itemised difference. This is Maturity Level 3.

Phase 2 · Days 90-180 — Establish the forward view

Objective. Move from an accurate present to a defensible future.

- Replace single-point EACs with a published range and named assumptions.
- Introduce forecast scoring: retain each forecast, compare to outturn at the next two gates.
- Assign a named owner and due date to every open variance. Publish the count of unassigned variances as a KPI in its own right.
- Reduce total control latency: measure the gap between data date and decision forum, and compress it.

Gate 2. A forecast range exists with stated assumptions, and every open variance has an owner. This is Maturity Level 4.

Phase 3 · Days 180-365 — Steer, then augment

Objective. Make forecasts consequential, and only then introduce AI.

- Establish a standing decision forum with authority to act, meeting inside the latency window.
- Trace decisions back to the forecasts that caused them, and forward into the baseline.
- **Only now**, introduce AI at rungs L2 and L4 — anomaly detection and classification — against a ledger that is known to be clean.
- Record the audit trail for every AI-assisted output.

Gate 3. A decision made this quarter can be traced to a specific forecast and shown landing in the baseline. This is Maturity Level 5.

Callout — the sequencing rule. AI enters at Phase 3, not Phase 1. A model trained on a ledger that fails Gate 1 will reproduce that ledger's errors with more confidence and better formatting. Organisations that invert this order buy an expensive amplifier for a signal they have not yet cleaned.

Figure 7 — suggested diagram. A horizontal 12-month timeline, three phases as coloured bands, three gates as vertical markers with their test written beneath. A separate track along the bottom labelled "AI readiness", shaded grey until Phase 3 where it activates.

16. Worked case — the cost of a cut-off gap

Illustrative composite. The figures below are arithmetically consistent and constructed to demonstrate the method. They are not drawn from a single named project, and no client data is represented.

Setting. A hyperscale data-centre programme. Budget at completion 420,000,000. Duration 30 months. Data date: month 14.

Reported position at month 14

Measure	Value
Planned value (PV)	168,000,000
Earned value (EV)	151,200,000
Actual cost, as invoiced	158,000,000
Subcontract work performed, not yet invoiced	12,400,000
Contingency held	21,000,000 (5% of BAC)

Step 1 — the position as reported. Using invoiced cost only:

- $CPI = 151,200,000 \div 158,000,000 = \mathbf{0.957}$
- $SPI = 151,200,000 \div 168,000,000 = \mathbf{0.900}$
- $EAC (BAC \div CPI) = 420,000,000 \div 0.957 = \mathbf{438,900,000}$

The reading: mild cost pressure, a schedule problem, an overrun of about 19 million against a 21 million contingency. Uncomfortable but contained. **This is the report that goes to the board.**

Step 2 — the position with the accrual booked. True actual cost = 158,000,000 + 12,400,000 = **170,400,000**.

- $CPI = 151,200,000 \div 170,400,000 = \mathbf{0.887}$
- $EAC (BAC \div CPI) = 420,000,000 \div 0.887 = \mathbf{473,300,000}$

The cut-off gap alone moved the forecast by 34,400,000 — more than the entire contingency of 21,000,000. The project was not mildly exposed. It had already consumed its contingency and more, and the report said otherwise.

Step 3 — the forecast range. With the corrected cost, three defensible EACs, each resting on a different assumption:

Assumption	Formula	EAC	Variance at completion
The overrun was a one-off; remaining work performs to plan	$AC + (BAC - EV)$	439,200,000	-19,200,000
Cost performance to date persists	$AC + (BAC - EV) \div CPI$	473,300,000	-53,300,000
Both cost and schedule pressure persist	$AC + (BAC - EV) \div (CPI \times SPI)$	507,000,000	-87,000,000

The deliverable is the range, not a number. 439 to 507 million. The professional's task is to state which assumption the organisation is choosing and why — and the choice is a management decision, not an arithmetic one.

Step 4 — the diagnosis. Note where this failed. Not in the forecasting. The EAC formulae were applied correctly at every stage. The failure was at **conversion 1** — reality entering the record — and it propagated undetected through every downstream calculation.

Against the Control Effectiveness Equation: fidelity was approximately 0.89 on the cost term. Timeliness and authority were both good. The organisation's controls investment had gone into conversions 3 and 4, exactly as Section 4 predicts.

Step 5 — where AI belongs here. An anomaly-detection model over the commitment ledger, comparing goods-received-not-invoiced against booked accruals by control account, would have flagged this gap in month 9. That is **Assurance Ladder L2** — the model detects, a professional verifies each flag, and a human decides.

The model does not book the accrual. It does not sign the forecast. It shortens the distance between an error occurring and a professional seeing it, which is the entire value proposition of AI in project controls.

At month 9, sixteen months of the programme remained. At month 14, that had fallen to sixteen months minus five — and the options available at each point were materially different. That gap is what "knowing early" is worth.

Figure 8 — suggested diagram. A dual-line chart: reported EAC versus true EAC, months 6 to 14, with the divergence shaded and labelled "34.4m concealed". A horizontal line at BAC + contingency showing when the true line crosses it, and a vertical marker at month 9 labelled "detectable here".

17. Common mistakes and lessons learned

Mistake 1 · Buying a tool to fix a governance problem. The most common and most expensive error. If variances have no owners, no dashboard will create one. Diagnose the binding term in $E = F \times T \times A$ before procuring.

Mistake 2 · Treating the forecast as a report rather than a decision instrument. A forecast produced, circulated and filed has done nothing. The test of a forecasting process is the decision log, not the report pack.

Mistake 3 · Accepting progress from the party being measured. A contractor's percentage complete is a commercial position, not a measurement. This is not an accusation of bad faith; it is a structural conflict that measurement rules exist to remove.

Mistake 4 · Quoting a single EAC. A single number implies a certainty the method cannot support and conceals the assumption that generated it. State the range and name the assumption.

Mistake 5 · Allowing a standing reconciliation difference. "The usual difference" is the most dangerous phrase in a controls review. A difference that is characterised rather than itemised is an unexamined error.

Mistake 6 · Deploying AI onto unreliable data. Covered in Sections 11 and 15. The model amplifies whatever condition the data is in.

Mistake 7 · Confusing fluency with correctness in AI output. Generated commentary reads well by construction. Legibility is not evidence. Require the verification step, and record who performed it.

Mistake 8 · Rebaselining to hide variance rather than to reflect approved change. A baseline that moves to match actuals has stopped being a control. Rebaselining is legitimate only as the implementation of approved change, and the sum of approved change must reconcile to the baseline delta.

The lesson beneath all eight. Every one is a failure of discipline, not of capability. None requires new technology to solve, and none is solved by new technology alone.

18. Future outlook — five shifts

One. Continuous position replaces periodic close. As commitment and progress data become available in near-real time, the monthly cycle becomes a governance rhythm rather than a data constraint. The advantage goes to organisations whose conversion 1 is already clean — for everyone else, faster data means faster propagation of the same errors.

Two. Assurance becomes the scarce skill. As drafting, extraction and screening are automated, the differentiating professional capability shifts from producing analysis to interrogating it. The question moves from "what does the number say" to "what would have to be true for this number to be wrong".

Three. The audit trail extends to the machine. Expect increasing insistence — from auditors, boards and eventually contracts — that AI-assisted outputs carry a record of what was asked, what was produced and who accepted it. Organisations that build this trail early will absorb the requirement without disruption.

Four. Hybrid delivery makes classical controls harder, not obsolete. As predictive governance meets adaptive execution, earned value and phase-gate reporting must span both. The demand for professionals who can carry cost discipline into sprint-based delivery will rise, not fall. This is why Domain 9 exists.

Five. Data condition becomes a competitive asset. An organisation with fifteen years of clean, well-structured project data can train models that its competitors cannot. This favours long-term data discipline over short-term tool adoption, and the advantage compounds.

Callout. Each shift rewards the same underlying investment: a trustworthy record and a governed decision loop. None rewards tooling purchased ahead of that.

19. Key takeaways

1. Project controls is the discipline of knowing early enough to act — not of reporting accurately after the fact.
2. Control effectiveness is multiplicative: $E = F \times T \times A$. Diagnose the binding term before spending.
3. A control system performs six conversions. Conversions 1 and 6 — where reality enters and where decisions land — are the least governed and the most damaging.
4. The most expensive failures are silent: confident, consistent reports built on flawed inputs.
5. Financial literacy is a controls competency. A function that cannot reconcile to the finance ledger is running a second set of books.
6. A single-point EAC is not a forecast. The range and the named assumption are the deliverable.
7. Every variance needs a name and a date. This is the cheapest available improvement in most organisations.
8. AI changes the cost of analysis, not the location of accountability. **AI proposes; the professional disposes.**
9. Place AI tasks on the assurance ladder by consequence of undetected error, not by demonstrated capability.
10. Clean the record before you model it. AI on poor data produces the same errors with more confidence.

20. The Controls Assurance Checklist

Thirty-one tests, grouped by conversion. Intended for a controls health check, an internal audit scope, or a due-diligence review. Each item is answerable **yes** or **no** — a qualified answer counts as no.

Conversion 1 · Reality → Record

1. Is the cut-off date fixed, published, and unchanged for the last six periods?
2. Are goods-received-not-invoiced reconciled to booked accruals each period?
3. Is the resulting difference itemised rather than characterised?
4. Are subcontractor commitments visible before invoice?
5. Can a sampled cost be traced from source document to reported position in under an hour?

Conversion 2 · Record → Structure

1. Is there a documented mapping between WBS, CBS and the chart of accounts?
2. Is that mapping reviewed whenever either structure changes?
3. Is cost coded at commitment rather than at invoice?
4. Is the miscoding rate measured?

Conversion 3 · Structure → Position

1. Is a measurement method defined per work package before work starts?
2. Is every progress figure generated by a physical rule rather than a judgement?
3. Is progress independent of the party being measured?
4. Does the controls cost position reconcile to the finance ledger every period?
5. Is there any standing unreconciled difference? (A yes here is a fail.)
6. Are earned value indices calculated on accrual-corrected actual cost?

Conversion 4 · Position → Forecast

1. Is the EAC published as a range rather than a single point?
2. Is the assumption behind each EAC scenario stated in writing?
3. Are past forecasts retained and scored against outturn?
4. Is contingency drawdown tracked against the risk register that justified it?
5. Is schedule risk quantified rather than asserted?
6. Is the basis of estimate documented and version-controlled?

Conversion 5 · Forecast → Decision

1. Does every open variance have a named individual and a due date?
2. Is the count of unassigned variances reported as a KPI?
3. Is the gap between data date and decision forum measured?
4. Is that gap shorter than the window in which the decision can still change the outcome?
5. Does reporting lead with exceptions rather than completeness?

Conversion 6 · Decision → Reality

1. Does the sum of approved change reconcile to the delta between original and current baseline?
2. Is rebaselining permitted only as implementation of approved change?
3. Can a decision from last quarter be traced to the forecast that caused it?

Across the loop · AI assurance

1. Is every AI-assisted output placed on an assurance rung by consequence of undetected error?
2. Is there a record of what the tool was asked, what it produced, and who accepted it?

Scoring guidance. Fewer than 20 of 31: the organisation is at Maturity Level 2 or below, whatever its tooling. Items 13, 14, 22 and 29 are load-bearing — failing any one of them caps effective maturity regardless of the rest.

21. Key definitions and glossary

Term	Definition as used in this publication
Accrual	Recognition of a cost incurred but not yet invoiced, in the period in which it was incurred
Actual cost (AC / ACWP)	Cost genuinely incurred for work performed, including accruals
Baseline	The approved, version-controlled plan against which performance is measured
Basis of estimate	The documented assumptions, methods, sources and exclusions underpinning an estimate
Budget at completion (BAC)	The total authorised budget for the scope of work
Contingency	Funds held within the baseline for identified risks that may occur
Control account	The management-control point where scope, budget, actual cost and schedule integrate
Cost breakdown structure (CBS)	Hierarchical decomposition of project cost by cost element or type
Cost performance index (CPI)	Earned value divided by actual cost; cost efficiency to date
Cut-off	The fixed date at which a reporting period's transactions close
Decision latency	Elapsed time between an event occurring and a decision being taken on it
Earned value (EV / BCWP)	Budgeted cost of work actually performed
Estimate at completion (EAC)	Forecast total cost of the project at completion
Estimate to complete (ETC)	Forecast cost of the remaining work
Float	Time an activity can slip without delaying a successor (free) or the project (total)
Goods received not invoiced (GRNI)	Value received from suppliers for which no invoice has yet been processed
Management reserve	Funds held outside the baseline for unidentified risk, released by governance
Planned value (PV / BCWS)	Budgeted cost of work scheduled by the data date
Provision	A liability of uncertain timing or amount, recognised when criteria are met
Rebaselining	Formal revision of the approved baseline to implement approved change
Schedule performance index (SPI)	Earned value divided by planned value; schedule efficiency in cost terms
To-complete performance index (TCPI)	Cost efficiency required on remaining work to achieve a stated target
Variance at completion (VAC)	Budget at completion less estimate at completion
Work breakdown structure (WBS)	Hierarchical decomposition of project scope into deliverables and work packages

Frameworks introduced in this publication

Framework	Section	Purpose
The Controls Value Chain	4	Six conversions; locates where fidelity and time are lost
The Control Effectiveness Equation	5	$E = F \times T \times A$; identifies the binding constraint
The Seven Silent Failures	6	Failure modes that produce plausible reports, with detection tests
The Three Literacies	7	Explains the 40/40/20 competency weighting
The AI Assurance Ladder	12	Places AI tasks by consequence of undetected error
The Controls Maturity Model	13	Five levels defined by demonstrated capability
The Twelve Disciplines	14	Auditable practices, two per conversion
The Controls Assurance Checklist	20	Thirty-one binary tests for a health check

23. About PCI AI

PCI AI · Project Controls Institute Global, Inc. is a certification body for project-controls professionals, incorporated as a Delaware Non-Stock Corporation.

The Institute's position is that project controls has changed in one specific way — a capable new tool now sits on every practitioner's desk — and that a credential should certify both the classical discipline and the judgement to use that tool responsibly. Hence the governing principle applied throughout its work: **AI proposes; the professional disposes.**

The Institute publishes its Body of Knowledge, examination content outline and candidate materials openly, so that professionals can study, evaluate and challenge the framework before deciding whether the credential is right for them. Education comes first.
